

Financial News Sentimental Analysis and their Correlation with Daily Trade Volume

Final project for INST447, Spring 2026

Ifa Bato, Ashton Kabou, Gene Ni, Nebeyu Tsigea, Rachel Wang

Executive Summary

This project is designed for investors who hold positions in publicly traded stocks, particularly focused on Apple (AAPL). It may be hard to consistently monitor the constant stream of financial news, analyst opinions, and quantitative commentary that surrounds their investments. Rather than tracking prices, which investors can observe directly, our tool focuses on the sentiment landscape of the news and public conversations around the stock, giving the users a quick pulse on whether the coverage is heading towards positive, negative, or neutral and what stocks lead in that direction. The primary data source is the Finnhub financial news API, which looks at articles from major outlets including Yahoo Finance, Benzinga, SeekingAlpha, CNBC, ChartMill, and Finnhub's own feed. The trade volume data is pulled from Yahoo Finance from the yfinance library. The trade volume is used to compare if positive or negative sentiment has an impact on the trade volume of AAPL.

The key findings were from the 150+ news articles over May 1–2, 2026 using the FinBERT model; it skewed meaningfully positive, driven by Apple's blowout fiscal Q2 2026 earnings report, which recorded a revenue of \$111.2B. This was caused by a 22% surge in iPhone sales, a \$100B share buyback, and beating Wall Street estimates. Neutral was the second most common label, showing market context articles that mentioned AAPL without taking a specific stance. Negative sentiment was a minority but clustered around real concerns, such as the "RAMageddon", the supply constraints of Mac items, and geopolitical tariff risks. A notable bias finding was source concentration, Yahoo Finance dominated the dataset by volume, which means the way they edit their articles largely shapes the overall sentiment distribution. FinBERT confidence was generally high (median above 0.87), with lower confidence observed on mixed or ambiguous articles, validating the model's calibration on financial text. Along with that there is strong evidence of the news sentiment following the overall trend of the stock. Meaning negative sentiment means overall less trades, and high sentiment pushes for higher trade volume. As AAPL is an overall bullish stock, the high confidence of traders means that negative sentiment usually causes hesitation and not a sell off.

The most technically challenging aspect was trying to integrate the FinBert pipeline to work with the full ETL workflow. It was really difficult to manage the limits, and cleaning the characters, and handling API summaries that cut off mid sentence. It was also hard to get started, trying to find a stock that had a multitude of sources that weren't all biased was something that took time to compile. It was also very interesting to determine how to handle articles that mentioned AAPL broadly, especially since they were more focused on the market rather than Apple specifically. The source bias analysis really highlighted how diverse the dataset is yet still so concentrated with so much data.

Project library imports:

```
import requests
from dotenv import load_dotenv
import yfinance as yf
import os
from transformers import pipeline
from datetime import datetime, timedelta
import time
import pandas as pd
import seaborn as sns
import matplotlib.pyplot as plt
```

Load environment variables:

```
load_dotenv()
```

True

Extra Mile Details

Our extra mile points went into the extraction and merging code and data visualization portions of the project. Starting with the extraction, we had to go the extra mile by using two APIs to collect the data for our dataset rather than having a .csv file ready to be loaded into a DataFrame right away. This meant we had to take additional steps to figure out what the APIs returned and how to best extract the parts we wanted from what was returned. Our goal for the extraction portion was to combine news data and finance data together so we could use it further down the process for comparison stats. Regarding the data visualization portion, we had to put extra effort in ensuring that all 11 variables had a visualization, especially when we realized later on that one of the earlier functions wasn't used, and that meaningful relationships were being captured. Our goal with the visualizations was to extract insights from the data about how market sentiment related to daily trade volume, or if it had any relation to begin with.

Source(s) & Extraction

We are extracting data from two main sources: yFinance (<https://ranaroussi.github.io/yfinance/>) and Finnhub Market News API (<https://finnhub.io/docs/api/market-news>). Yahoo! finance data is extracted directly from the package's underlying requests to Yahoo's api. You can view the data without the API from Yahoo Finance (example with AAPL - <https://finance.yahoo.com/quote/AAPL/>). Finnhub News API obtained their data through either contracts with news companies, or they obtained it through public databases and scraping it themselves. But Looking at their professionalism and accuracy based on the timestamps, I believe they are in some sort of agreement with all the major news sources therefore allowing them to use their news metadata and sell them. The headlines themselves are generated by authors from those respective news outlets. The summaries however, may have a chance of being generated by AI. Yahoo Finance data are free for anyone and is not accurate in the sense that it does not show both live data and sub-minute ticks. Therefore it leads me to believe that Yahoo Finance also has a deal with major exchanges to display this data for free, to the public. Since it is minute-ticks, this means that the provider, or Yahoo themselves calculated high, low, volume and other fields values to be displayed.

First the variable of note for yFinance is the 'Volume' since we are trying to compare whether news sentiment has an impact on the trade volume of that specific stock.

Example of the data obtained from yFinance `ticker.history(start=start_date, end=end_date)`:

Table 1: Sample row returned by yFinance for AAPL

Date	Open	High	Low	Close	Volume	Dividends	Stock Splits
2026-05-01 00:00:00-04:00	278.60329	286.95561	278.11375	279.88214	179915400	0.0	0.0

This is a sample of what we obtained as a return from yFinance. We specifically will be using the 'Volume' column.

Variable name - Volume (integer) The number of trades conducted on that day is related to that specific ticker.

As for Finnhub, we extracted news data from their api and it returns the following:

```
[
  {
    'category': 'company',
    'datetime': 1622505600,
```

```

    'headline': 'Apple announces new iPhone',
    'id': 123456,
    'image': 'https://example.com/image.jpg',
    'related': 'AAPL',
    'source': 'Reuters',
    'summary': 'Apple has announced the release of its new iPhone model, which features a large',
    'url': 'https://www.reuters.com/article/us-apple-iphone-idUSKCN2D90XG'
  },
]

```

```

[{'category': 'company',
  'datetime': 1622505600,
  'headline': 'Apple announces new iPhone',
  'id': 123456,
  'image': 'https://example.com/image.jpg',
  'related': 'AAPL',
  'source': 'Reuters',
  'summary': 'Apple has announced the release of its new iPhone model, which features a large',
  'url': 'https://www.reuters.com/article/us-apple-iphone-idUSKCN2D90XG'}]

```

This is a sample of what is returned when we called:

```

"https://finnhub.io/api/v1/company-news?symbol={ticker}&from={start_date}&to={end_date}&token

```

```

'https://finnhub.io/api/v1/company-news?symbol={ticker}&from={start_date}&to={end_date}&token

```

We will be using all of these fields for analysis later on, but the main three variables we will be using for our sentiment analysis is the following: ‘datetime’ (unix timestamp - integer) to determine when the article is released. This is crucial because we will eventually be conducting multi-day analysis and we need to separate articles by date. ‘headline’ (string) and ‘summary’ (string) are both used to construct ‘text’ in a later data structure which is used in the sentiment analysis engine. We combine both ‘headline’ and ‘summary’ with a ‘;’ as the separator to form ‘text’(string). This is because finBERT takes a string of text as input and we want to capture both the summary and the headline as input, without losing any context.

The other variables are used in later supplemental analysis. The main one is ‘source’ which we will compare which source is the most bullish or bearish and who is reporting on that specific ticker.

Variable name - “datetime” (integer) The unix timestamp of when the article came out.

Variable name - “headline”(string) The title of the article.

Variable name - “summary” (string) The description of the contents of the article.

Variable name - “source” (string) The name of the news outlet that wrote the article.

Obtaining and combining data from two separate data sources in preparation for analysis is one of the hardest parts of the project. We first obtain the volume data from yFinance using the `get_volume_data`.

```
def get_volume_data(ticker, start_date, end_date):
    """Fetches the volume of trades conducted on the specified company and date.

    Args:
        ticker (str): Stock ticker symbol
        start_date (str): Start date in the format YYYY-MM-DD
        end_date (str): End date in the format YYYY-MM-DD

    Returns:
        pandas.Series: A series containing the volume of trades for the specified company and date
    """
    ticker = yf.Ticker(ticker)
    hist = ticker.history(start=start_date, end=end_date)
    return hist["Volume"]
```

This function obtains and returns the trade volume of a given stock for the given time duration. The ticker (example: AAPL) is passed into the `yf.Ticker` class to obtain the ticker specific information. We then access the history by calling the `history()` method from the `Ticker` class, passing in a start and end date to get the volume data from that range.

```
def get_news_company(ticker, start_date, end_date):
    """Fetches news articles from Finnhub for a specific company within a given date range.

    Args:
        ticker (str): Stock ticker symbol
        start_date (str): Start date in the format YYYY-MM-DD
        end_date (str): End date in the format YYYY-MM-DD

    Returns:
        list: A list of news articles for the specified company and date range in this format
        [
            {
                'category': 'company',
                'datetime': 1622505600,
                'headline': 'Apple announces new iPhone',
            }
        ]
    """
```

```

        'id': 123456,
        'image': 'https://example.com/image.jpg',
        'related': 'AAPL',
        'source': 'Reuters',
        'summary': 'Apple has announced the release of its new iPhone model, which f
        'url': 'https://www.reuters.com/article/us-apple-iphone-idUSKCN2D90XG'
    }
]
"""
api_key = os.getenv("FINNHUB_API_KEY")
url = f"https://finnhub.io/api/v1/company-news?symbol={ticker}&from={start_date}&to={end
r = requests.get(url)

if r.status_code == 200:
    return r.json()
else:
    print(f"Error fetching news data: {r.status_code}")
    return None

```

The function above fetches the company headline and summary using the Finnhub API when given a specific ticker symbol, a start and end date. The api requires an api key which is imported with the `python_dotenv` package. It uses the `request` function from the `requests` package to conduct the api request. It also has simple error handling for any unexpected behaviors. The description of the function also provided an example of the return values.

```

def get_news_range(symbol, start_date, end_date):
    """Get the news based on the range of the dates. Increments a day at a time to bypass re

    Args:
        symbol (str): The symbol you are trying to fetch
        start_date (str): Start date in %Y-%m-%d
        end_date (str): End date in %Y-%m-%d

    Returns:
        [dict]: List of all the article metadata
    """
    start = datetime.strptime(start_date, "%Y-%m-%d").date()
    end = datetime.strptime(end_date, "%Y-%m-%d").date()

    all_news = []
    cur = start
    print("Begin fetching news articles:")

```

```

while cur < end:
    day_str = cur.strftime("%Y-%m-%d")
    chunk = get_news_company(symbol, day_str, day_str) or []
    all_news.extend(chunk)
    cur += timedelta(days=1)
    time.sleep(0.05)
    print("Day:", cur)

return all_news

```

get_news_range extends on the get_news_company function to obtain news articles that are more than a day. This is important because for financial analysis we usually only see the effect over a long period of time, therefore we would require the fetching of a range of dates. Finnhub also has a limit to how many news articles it could send, and for long range dates, it often silently drops those dates.

```

def data_transformation_engine(news_raw, volume):
    """Combines both yFinance volume data and Finnhub article data.
    Finnhub articles use unix time, which needs to be converted to string time.
    Also converts the Series integer data structure in pandas to python primitive int.
    Iterates through both news and volume data inputs and combines them into a single dataset.

    Args:
        news_raw (list(dict)): A giant list of dictionaries containing metadata information
        volume (pandas.Series): A pandas series of dates and the traded volumes

    Returns:
        _type_:

        type dataset:
            key: date strings in the format of "%Y-%m-%d"
            value: Day

        type Day:
            'articles': [Article] --> list of articles
            'volume': int

        type Article:
            "ticker": str,
            "headline": str,
            "summary": str,
            "text": str,

```

```

        "source": str,
        "date": datetime
    """
    dataset = {}
    news = transform_news_data(news_raw)

    vol_by_date = {}
    for ts, vol in volume.items():
        date_str = ts.strftime("%Y-%m-%d")
        vol_by_date[date_str] = int(vol)

    for article in news:
        date = article['date']
        if date not in vol_by_date:
            continue
        if date not in dataset:
            dataset[date] = {
                'articles': [article],
                'volume': vol_by_date[date],
            }
        else:
            dataset[date]['articles'].append(article)

    # print("Verification:")
    # for d in dataset:
    #     print(d, len(dataset[d]['articles']), dataset[d]['volume'])

    return dataset

```

The snippet above is code from the `multiday_financial_news_sentiment_pipeline` where the extraction code is obtained and combined with the data transformation engine. The `transform_news_data` returns the cleaned, and processed article information containing the ‘text’ field which is the combination of ‘headline’ and ‘summary’ fields.

```

vol_by_date = {}
for ts, vol in volume.items():
    date_str = ts.strftime("%Y-%m-%d")
    vol_by_date[date_str] = int(vol)

```

This snippet changes the string time to the proper format so it could be the same as the volume dates.

```

for article in news:
    date = article['date']
    if date not in vol_by_date:
        continue
    if date not in dataset:
        dataset[date] = {
            'articles': [article],
            'volume': vol_by_date[date],
        }
    else:
        dataset[date]['articles'].append(article)

```

Next, we generate the “day” data structure by constructing a dictionary that has two fields:

```

dataset[date] = {
    'articles': [article],
    'volume': vol_by_date[date],
}

```

This is the basic structure of a “day”. It contains a list of all the articles, and has the volume for the day. The ‘date’ serves as the primary key that connects the two datasets following the format “%Y-%m-%d”.

Data_transformation_engine function takes in inputs from both get_news_company and get_volume_data formats and then merges them into a single data structure. The data is finally returned as a big structure like the following:

```

type dataset:
    key: date strings in the format of "%Y-%m-%d"
    value: Day

type Day:
    'articles': [Article] --> list of articles
    'volume': int

type Article:
    "ticker": str,
    "headline": str,
    "summary": str,
    "text": str,
    "source": str,
    "date": datetime

```

The main results of the merging of the code returns a list of “days”. This is so that the analysis could iterate over this later for visualization and ease of calculation. Visualizations use daily data as the bars in the bar chart, so having each of them in lists assists in decreasing the complexity later down the line.

Transformation Processes

```
def transform_news_data(news_data):

    transformed = []

    for article in news_data:

        headline = article.get("headline", "")
        summary = article.get("summary", "")

        # combine text
        text = f"{headline}. {summary}"

        # cleaning
        text = text.replace("\xa0", " ")
        text = text.replace("&#39;", "'")
        text = " ".join(text.split())
        text = text.encode("utf-8", "ignore").decode("utf-8")

        # convert timestamp
        date = datetime.fromtimestamp(
            article["datetime"]
        ).strftime("%Y-%m-%d")

        transformed.append({
            "ticker": article.get("related"),
            "headline": headline,
            "summary": summary,
            "text": text,
            "source": article.get("source"),
            "date": date
        })

    return transformed

The transformation stage focused on converting raw financial news data into a clean and structured dataset suitable for sentiment analysis and exploratory data analysis (EDA). The raw data was extracted from the Finnhub API and initially contained nested JSON objects with unnecessary metadata, inconsistent formatting, and timestamp values that were not human-readable. Several transformation steps were performed to improve data quality, consistency, and usability. First, relevant attributes were selected from the raw API response, including the stock ticker symbol, article headline, summary, source, and publication date. This reduced unnecessary information and ensured the final dataset only contained variables relevant to the project objectives.

Next, the headline and summary fields were combined into a single text field. This was done because sentiment analysis models generally perform better with more contextual information rather than short headlines alone. Combining both fields allowed the sentiment model to capture additional financial context from the article summaries.

Text-cleaning transformations were then applied to standardize the article content. Special characters such as non-breaking spaces and HTML escape characters were removed or replaced to improve readability and prevent encoding issues during analysis. Extra whitespace was also removed using string normalization techniques. Additionally, UTF-8 encoding and decoding

were applied to handle malformed characters and ensure consistent text formatting across all articles.

The Unix timestamp values provided by Finnhub were transformed into human-readable dates using Python's datetime module. This made the dataset easier to interpret and enabled later temporal analysis of sentiment trends over time.

After cleaning and restructuring the data, the transformed text was processed using the FinBERT sentiment analysis model from Hugging Face Transformers. FinBERT is specifically trained on financial text, making it more appropriate for financial news sentiment classification than general-purpose sentiment models. Each article received a sentiment label (positive, negative, or neutral) along with a confidence score representing the model's certainty.

Finally, all transformed and enriched records were stored in a list and converted into a Pandas DataFrame. This final structured dataset served as the project's final data product and was later used for descriptive and bias-related exploratory data analysis.

The transformation decisions were guided by the project goal of analyzing relationships between financial news sentiment and stock-related discussion trends. Ensuring clean, standardized, and context-rich text data was important for improving the reliability of the sentiment analysis results and supporting accurate downstream analysis.

```

Expected Distributions

Several variables followed anticipated patterns given the financial nature of the data:

- **Ticker Distribution:** As expected, the Ticker Distribution shows 100% of the 174 articles belong to “AAPL.” This is expected as the extraction script was specifically scoped to this ticker.
- **Articles Published Per Day:** The Articles Published Per Day graph shows a massive spike on 2026-05-01. This aligns with the “Apple Q2 Earnings” headlines noted in the output, as earnings reports typically trigger a high volume of immediate coverage.

- Combined Text Word Count Distribution: The distribution graph is right-skewed, which is typical for news data. Most articles consist of a concise headline and a short summary (averaging ~44 words), while a few outliers provide much more extensive context.
- Sentiment Distribution: The Sentiment Distribution is predominantly positive. Given that the headlines mention Apple “beating estimates” and hitting “record highs,” a positive skew is the logical outcome of a strong earnings report.

Unexpected Distributions and Observations

Some variables revealed more nuanced or surprising trends:

- Distribution of FinBERT Confidence Scores: While one might expect a normal distribution the graph shows a strong left skew. The model is highly confident (>0.90) for a large portion of the data (79 articles). This suggests the language used in these financial reports is very explicit and aligns well with FinBERT’s training data.
- Confidence by Sentiment: The “positive” sentiment boxplot shows many low-confidence outliers. This is unexpected because positive news is usually straightforward; however, it suggests some “positive” articles might contain mixed language (e.g., “Apple Surged... 3 Concerns Lurking Beneath”) that dampens the model’s certainty.
- Sentiment by News Source: The Sentiment by News Source chart reveals significant source bias. Yahoo is overwhelmingly positive, while CNBC appears almost exclusively neutral in its reporting style for this period. This highlights how the choice of data source can fundamentally shift the perceived market sentiment.
- Sentiment Distribution Over Time: The sentiment shifted from neutral/positive on April 30th to overwhelmingly positive on May 1st (Earnings Day), before cooling back toward neutral on May 2nd. The rapid “digestion” of the news by the market is clearly visible here.

Bias-Related EDA Code

Bias-Related EDA Narrative From the analysis of the financial news dataset for Apple (AAPL), we looked at key sources of bias that had the most effect on the dataset's conclusions.

Source Imbalance: Yahoo Finance made up a wide share of the dataset, contributing to about 105 of the 174 articles collected. When one source accounts for nearly two thirds of your data, the overall judgement stops reflecting the broader financial media landscape and starts reflecting that one source's voice. This is not a mistake that happens during analysis but rather a consequence of the way the data was pulled. The Finnhub API takes from a fixed pool of partner sources, so the imbalance was baked in from the moment collection began. Looking at how sentiment broke down by source makes this problem concrete. CNBC came in almost entirely neutral across its articles and ChartMill was neutral across every single one of its contributions, yet because Yahoo so heavily outnumbers both of them, their tone barely registers in the overall picture. The dataset reads as more bullish than it probably should, not necessarily because the market was that optimistic, but because the loudest voice in the room happened to lean that way.

Sentiment Skew from Collection Window: The overall sentiment data was 51.1% positive, 33.3% neutral, and 15.5% negative which heavily shaped when the data was collected. The two-day window of May 1-2, 2026 coincided directly with Apple's blowout Q2 earnings report, a strongly positive market event. Collecting data during a major report beat means that the inherent positive bias that would not exist during a neutral or negative market period. This limits how broadly any conclusions can be generalized — the findings describe sentiment during one exceptional event, not typical market conditions for AAPL.

Model Confidence on Negative Sentiment: Negative articles had the lowest average FinBERT confidence at 0.786, compared to 0.858 for positive and 0.835 for neutral. This suggests the model is least certain when classifying bearish or mixed language, which is particularly relevant for articles that discuss conflicting signals — such as Apple's record earnings alongside rising memory costs and Mac supply constraints. These articles may be forced into a single label that does not fully capture their nuance. A worthwhile follow-up would be applying a confidence threshold to flag low-certainty classifications for manual review, or exploring multi-label approaches for articles with clearly mixed sentiment.

Data Product & Guide

```
## Variable descriptions
```

```
### Quantitative
```

```
sen_confidence (continuous/quantitative) - how certain Finbert is about its sentiment rating
```

```
headline_word_count (discrete/quantitative) - the number of words in the headline
```

```
summary_word_count (discrete/quantitative) - the number of words in the summary
```

text_word_count (discrete/quantitative) - the total number of words in the headline and summary

Qualitative

ticker (categorical) - a unique abbreviation for the name of the stock (e.g. AAPL for Apple)

headline* - the title for the news article; intended to grab the reader's attention and highlight key points

summary* - text that condenses the main points of the article; generated by Finnhub using NLP

text* - the headline and summary combined/concatenated with a space in between

source (categorical) - the news source that the article was published in

sentiment (categorical/qualitative) - general attitude towards a stock, which can be positive, neutral, or negative

Temporal

date (temporal) - the time the article was published in yyyy-mm-dd format

* the values for these variables are "free-response"-like or unique

User guide to running the code

1. Download the installer for Positron from this [link](#). Make sure to accept the license agreement by checking the box. Choose the file that matches your platform. The platform information is available if you visit System Information for Windows or About This Mac for MacOS.
2. Clone the repository from this using `git clone git@github.com:lejio/INST447-Final-Project.git` for SSH.
3. Open the “INST447-Final-Project” folder in Positron by clicking on the Open button with the file icon at the top left of the application.
4. Go to the terminal at the bottom half of the interface. Make sure that you are in the correct folder. Your path should have “INST477-Final-Project.” If not, use the `cd` command to get there. Here is a [tutorial](#) on using the command line.
5. Make a virtual environment by running `python3 -m venv .venv`.
6. Activate the environment using `source .venv/bin/activate` for MacOS/Linux. For Windows PowerShell, use `.\venv\Scripts\Activate.ps1`.
7. Install the dependencies from the `requirements.txt` file using `pip install -r requirements.txt`.
8. Check that quarto is installed in the environment using `quarto -v` in the terminal. If it isn't installed, install it using `brew install --cask quarto` for MacOS if you have Homebrew. If you're using Windows, you can install it from this [website](#) or using these instructions:

Copy and paste this in the command line if you are on linux to install quarto

```
# Get the latest .deb
wget https://quarto.org/download/latest/quarto-linux-amd64.deb

# Install it
```

```
sudo dpkg -i quarto-linux-amd64.deb
```

```
# Fix any missing deps if needed
```

```
sudo apt-get install -f
```

```
# Verify
```

```
quarto --version
```

You may have to restart Positron and your terminal after.

9. Also check that jupyter is installed using `jupyter --version`. If it isn't, run `python3 -m pip install jupyter` in the terminal.

10. Make sure that you're selecting the `.venv` interpreter session on the top right of the screen. Then you can run these commands in the terminal:

```
quarto preview inst447-group10-final-submission.qmd
```

or:

```
quarto render inst447-group10-final-submission.qmd
```
